SYLLABUS DEL CORSO

Fisiologia dei Sistemi

2324-3-E1301Q068

Aims

The course aims to provide the student in biological sciences with an overview of the structure (anatomy) and the mechanisms that govern the function of the organic systems. Organ physiology, in close relation to general physiology, is fundamental for the cultural background of biologists. Furthermore, **the organ physiology learned during the three-year degree in Biological Sciences is fundamental for further courses in the same field included in the master's degree in Biology.**

In particular, at the end of the course the student will have acquired the following skills:

- 1) knowledge and understanding: to have an integrated view of the organic systems from the functional point of view in order to better understand the organ physiology in the whole human organism;
- 2) applied knowledge and understanding: to be able to translate cellular physiology information to the organ physiology and apply what has been learned in basic physiology courses to the system physiology
- 3) making judgments: to be able to evaluate what has been learned with great critical point of view
- 4) communication skills: to communicate what has been learned with a correct scientific terminology
- 5) learning skills: to learn critically a large part of the scientific literature about the system physiology of the higher organisms

Contents

The course illustrates the function of most human organ systems, such as the somatic and autonomic nervous system, the endocrine, cardiovascular, respiratory, renal and digestive systems.

Detailed program

-Somatic nervous system: general concepts, nutrition and protection, glial cells. Anatomy of the sensory and motor system. Motor system: planning and execution of voluntary movement. pyramidal and extrapyramidal tracts. Parallel systems in the control of voluntary movement (cerebellum and nuclei of the base). Spinal reflexes.

-Autonomic nervous system: Orthosympathetic and Parasympathetic systems.

-Endocrine system: hormones and intracellular signals. Hypothalamic-hypophysis axis and related glands (thyroid, adrenal gland).

-Cardiovascular System: Heart, electrophysiology and mechanical function. Arterial and venous circulation. Capillary exchanges. Integrated homeostasis of arterial pressure and intravascular volume.

-Respiratory system: Respiratory mechanics. Alveolus-capillary exchanges. Gas transport in the blood. Pulmonary circulation and its regulation.

-Excretory system: Anatomic-functional organization of the renal parenchyma. Glomerular filtration mechanism and its regulation. Reabsorption and tubular secretion mechanisms. Renal clearance. Role of the kidney in the acid / base balance. Volume control, osmolarity and electrolyte concentrations.

-Digestive System: Digestion (cephalic, gastric, intestinal phases). Exocrine pancreas. Liver and bile formation. Absorption: sugars, amino acids, lipids, water. Transport of lipids in the blood.

Prerequisites

Knowledge of biochemistry, physics and general physiology

Teaching form

Frontal teaching and group works

Textbook and teaching resource

Textbook: "Fisiologia – Molecole, cellule e sistemi", D'Angelo E. & Peres A Eds, Edi Ermes.
Course slides on e-learning platform

Semester

Second semester

Assessment method

Written and oral exam. The written test is based on a series of multiple choice questions aimed at understanding if the student has learned the physiology of systems and if he has acquired an integrated view of organ physiology. The oral exam is aimed at understanding whether the student has learned communication skills related to organ physiology.
