SYLLABUS DEL CORSO

Introduction To Cosmology

2324-1-F5802Q004

Aims

The acquisition of a basic knowledge of the structure of the Universe and of the main stages of the cosmic history, from the big bang to the growth of structures.

By the end of the class the students:

1. will learn how to derive analitically or numerically the evolution of the main cosmological quantities (e.g. redshift, scale factor, luminosity and angular distances, cosmological horizon) starting from the density of the different components (e.g. relativistic and non relativistic matter, dark energy) permeating the Universe;
2. will be able to use cosmological and astrophysical observations to solve the inverse problem, i.e. to determine the values of the cosmological parameters from the information on the distributions of cosmological observables, as, for example, the distributions of redshift and luminosity distance pairs.

Contents

Classical cosmology, Friedman models. Cosmic microwave background. Cosmological nucleosynthesis. Inflation. Structure formation and growth.

Detailed program

Large scale homogeneity and isotropy of the Universe. The Hubble law. The Robertson Walker metric. The Friedmann Equation and Friedmann models. Measures of the cosmological parameters. Problems in the standard Big bang model and the inflation solution. Cosmic nucleosynthesis. Recombination. Cosmic microwave background. Gravitational instability in an expanding Universe. Differences in the distribution of

structures in presence of hot or cold dark matter.

Prerequisites

Mathematics and Physics for undergraduates. A basic knowledge of general relativity allows for a more complete comprehension of the class, but such knowledge is not necessary to fruitfully follow the class.
The first part of the course will include an introduction to the concepts of general relativity required.

Teaching form

Lessons (6 CFU). I will frequently propose during the lectures (not evaluated) questions and problems to be solved individually or in group, to allow for a check of the effective learning progress of the class.

Textbook and teaching resource

The main text of the class is: B. Ryden, “Introduction to cosmology”.

Some lectures, in particular on the structute formation topic, will be based on:

1. Binney and Tremaine "Galactic dynamics"
2. Longaire "Galaxy formation"

Semester

First semester.

Assessment method

The final exam is a viva on the topics discussed in class. there are no intermediate exams.

More specifically the exam consists of three parts: the discussion of an an argument picked by the student, the analysis of a multicomponent Friedmann model, and a third more general part to test the student's knowledge of the other argument discussed during the class.

Office hours

Wednesday 16:00-18:00
