Intuition:

- X is a set of alternatives with probabilities p(x). Only one alternative must occur (an outcome of an experiment, a received message, ...)
- How to quantify the information given by the fact that x occurs?
- if x = "tomorrow the sun will rise", p(x) = 0.9999.... The fact that the sun rises is not a surprise hence we have no uncertainty in anticipating it
- if x = "Fiorentina will won the Italian football championship", p(x) = 0.0001. If x occurs, it is unexpected, we have a huge amount of uncertainty in anticipating it

Shannon entropy (1948)

Goal: define a function *u* such that it is

a decreasing function: the more likely the occurrence of x, the less information is provided

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ □臣 ○のへ⊙

Shannon entropy (1948)

Goal: define a function u such that it is

a decreasing function: the more likely the occurrence of x, the less information is provided

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

• an additive function if $p(x, y) = p(x) \cdot p(y)$ then u(p(x, y)) = u(p(x)) + u(p(y))

Shannon entropy (1948)

Goal: define a function u such that it is

a decreasing function: the more likely the occurrence of x, the less information is provided

- an additive function if $p(x, y) = p(x) \cdot p(y)$ then u(p(x, y)) = u(p(x)) + u(p(y))
- ► the solution is u(p(x)) = K log_b p(x). If we measure uncertainty in bits then b = 2, u(¹/₂) = 1 (normalization condition) and so K = -1
- hence the information is $\log_2 p(x)$ bits

Let p(x) be a probability distribution on a finite set U
 H : P(U) → [0,∞)

(ロ)、(型)、(E)、(E)、(E)、(O)へ(C)

Let p(x) be a probability distribution on a finite set U
 H : P(U) → [0,∞)

$$H(X) = -\sum_{x \in X} p(x) \log_2 p(x)$$

it measures the expected information content of X

Hartley entropy (1928)

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

Let set
$$p(x) = \frac{1}{|X|}$$

 uncertainty associated with a choice among n = |X| alternatives/possibilities

Hartley entropy (1928)

Let set $p(x) = \frac{1}{|X|}$

- uncertainty associated with a choice among n = |X| alternatives/possibilities
- a measure of non-specificity: the fewer alternatives we have, the more specific is our choice

$$I(n) = \log_2 n$$

The amount of conflict of a focal set with all the other focal sets

$$con(m, m_A) = -\log_2(1 - \sum_{B \cap A = \emptyset} m(B)) = -\log_2 PI(A)$$

(ロ)、(型)、(E)、(E)、 E) の(()

Within a single body of evidence m

• Let
$$m_A(B) = \begin{cases} 1 & B = A \\ 0 & \text{otherwise} \end{cases}$$

The amount of conflict of a focal set with all the other focal sets

$$con(m, m_A) = -\log_2(1 - \sum_{B \cap A = \emptyset} m(B)) = -\log_2 Pl(A)$$

weigthed average over all focal sets:

$$E(m) = \sum_{A \in F} m(A) con(m, m_A) = -\sum_{A \in F} m(A) \log_2 PI(A)$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ □臣 ○のへ⊙

with F focal sets

If m is a probability distribution (probability assigned to singletons), E(m) is equivalent to Shannon entropy

If m is a probability distribution (probability assigned to singletons), E(m) is equivalent to Shannon entropy

Conflict is also named dissonance If the focal sets are consonant (not dissonant), A₁ ⊆ A₂ ⊆ ... A_n, then E(m) = 0 Possibility and necessity have no conflict

Confusion in Evidence

From conflict $E(m) = -\sum_{A \in F} m(A) \log_2 PI(A)$ To confusion

$$C(m) = -\sum_{A \in F} m(A) \log_2 \frac{Bel(A)}{Bel(A)}$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

Confusion in Evidence

From conflict $E(m) = -\sum_{A \in F} m(A) \log_2 PI(A)$ To confusion

$$C(m) = -\sum_{A \in F} m(A) \log_2 \frac{Bel(A)}{Bel(A)}$$

C(m) = 0 iff m(A) = 1 for one particular A and m(B) = 0 for all other B

Confusion in Evidence

From conflict $E(m) = -\sum_{A \in F} m(A) \log_2 PI(A)$ To confusion

$$C(m) = -\sum_{A \in F} m(A) \log_2 \frac{Bel(A)}{Bel(A)}$$

 C(m) = 0 iff m(A) = 1 for one particular A and m(B) = 0 for all other B

- C(m) characterizes
 - the uniformity of the distribution of the strength of evidence among the subsets
 - the multitude of subsets supported by evidence: the greater the number of subsets involved and the more uniform the distribution, the more we are confused

Specificity in possibility theory

• A generalization of Hartley entropy $I(n) = \log_2 n$

Specificity in possibility theory

- A generalization of Hartley entropy $I(n) = \log_2 n$
- Defined on ordered possibility distributions $\pi : \{x_1, x_2, \dots, x_n\} \mapsto [0, 1]$ $\forall i < j, \pi(x_i) \le \pi(x_j)$

$$U(\pi) = \sum_{i=1}^{n} (\pi(x_i) - \pi(x_{i+1})) \log_2 i$$

Specificity in possibility theory

- A generalization of Hartley entropy $I(n) = \log_2 n$
- Defined on ordered possibility distributions $\pi : \{x_1, x_2, \dots, x_n\} \mapsto [0, 1]$ $\forall i < j, \pi(x_i) \le \pi(x_j)$

$$U(\pi) = \sum_{i=1}^{n} (\pi(x_i) - \pi(x_{i+1})) \log_2 i$$

• Weighted average of Hartley measure for all focal elements A_i $U(\pi) = \sum_{i=1}^{n} m(A_i) \log_2 |A_i|$

Computational complexity

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

We have polynomial algorithms for all Ellerman entropies

- Iower, upper and mean: O(|U| * n * log₂ n) n = number of orthopairs
- average (in the case that $P_i \neq \emptyset$): $\Theta(n * |U|^2)$

Computational complexity

We have polynomial algorithms for all Ellerman entropies

• average (in the case that
$$P_i \neq \emptyset$$
): $\Theta(n * |U|^2)$

Shannon entropy: no simple algorithm to compute it

Goal: quantify the common information of two orthopartitions

(ロ)、(型)、(E)、(E)、 E) の(()

Goal: quantify the common information of two orthopartitionsThe mutual information

$$m(\mathcal{O}_1, \mathcal{O}_2) = h(\mathcal{O}_1) + h(\mathcal{O}_2) - h(\mathcal{O}_1 \wedge \mathcal{O}_2)$$

(ロ)、(型)、(E)、(E)、 E) の(()

where h is one of the entropies defined before

Goal: quantify the common information of two orthopartitionsThe mutual information

$$m(\mathcal{O}_1, \mathcal{O}_2) = h(\mathcal{O}_1) + h(\mathcal{O}_2) - h(\mathcal{O}_1 \wedge \mathcal{O}_2)$$

where h is one of the entropies defined before

Meet orthopartition

$$\mathcal{O}_1 \land \mathcal{O}_2 = \{ \mathcal{O}_{i1} \sqcap_t \mathcal{O}_{j2} | \mathcal{O}_{i1} \in \mathcal{O}_1 \text{ and } \mathcal{O}_{j2} \in \mathcal{O}_2 \}$$

with \sqcap_t the intersection defined by truth ordering

$$O_1 \sqcap_t O_2 = (L_1 \cap L_2, U_1 \cup U_2)$$

► The choice of ⊓_t is due to the fact that it holds:

 $\Pi_{\mathcal{O}_1 \land \mathcal{O}_2} = \{ \pi \land \sigma | \pi \text{ is consistent with } \mathcal{O}_1 \text{ and } \sigma \text{ is consistent with } \mathcal{O}_2 \}$
